AB - ZA9401443 The method involves monitoring the system in order to detect a connection of a fresh detonator to the system. When the connection is detected a unique address is assigned to the fresh detonator. The system is monitored by repeatedly transmitting a test signal to all detonators in the system from a control location. The detonators to which addresses have already been assigned are configured such that they don't respond to the test signal.

- A fresh detonator transmits a second signal to the control location in response to the test signal. The signal from the fresh detonator relates to its status. The test signal cannot arm or fire any of the detonators, since it is of limited energy and is encrypted.

- ADVANTAGE - Reduced wiring required due to unique identification of detonators.
